- 3 GPT: Introduction to RAG
- 4 Lab 7: Sentiment Analysis on Tweets

Overview: Topic 9

- 1 BERT
- 2 GPT: Hallucination
- 3 GPT: Introduction to RAG
- 4 Lab 7: Sentiment Analysis on Tweets

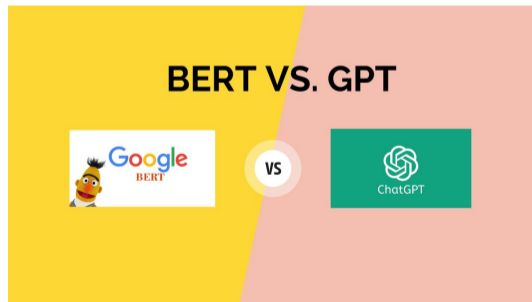

BERT: Motivation and Overview

- ▶ **BERT in a Nutshell:** BERT is a language model that understands the meaning of words by looking at the entire sentence, much like how we grasp context in everyday reading.
- ▶ **Why BERT is Powerful & Its Relation to Transformers:**
 - ▶ It builds on the Transformer architecture, which processes all words at once.
 - ▶ By using context from both before and after a word, BERT creates dynamic representations that adjust to different meanings.

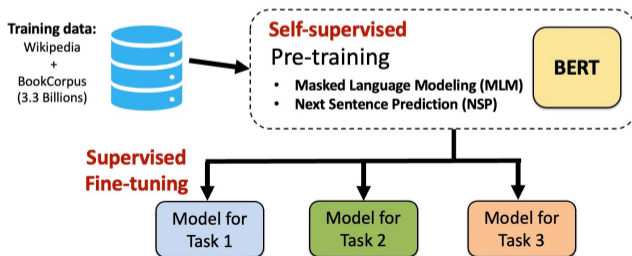

Evolution of Transformer Models

- ▶ Debut of Transformer in 2017 kickstarted a race to build on its innovative design
- ▶ In June 2018, OpenAI introduced GPT—a decoder-only model that excels in **Natural Language Generation (NLG)**, later powering ChatGPT.
- ▶ Four months later, Google released BERT—an encoder-only model specifically designed for **Natural Language Understanding (NLU)**.
- ▶ Both architectures yield very capable models, optimized for different tasks.

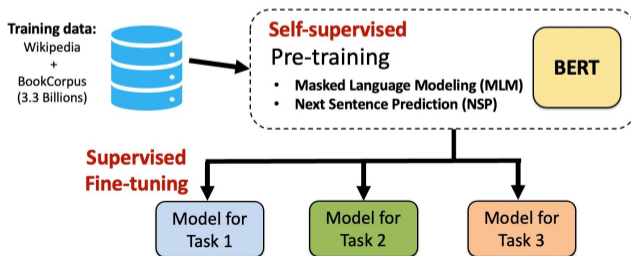

BERT Pre-training: Building the Foundational Model

- ▶ Pre-training involves training one large, task-agnostic model on a massive amount of text data.
- ▶ The model learns grammar, word usage, and common language patterns to form a “foundational” understanding of language.
- ▶ **Intuition:** Think of it as teaching someone to become fluent in English by exposing them to a wide variety of texts before they specialize in any one task.

BERT Fine-tuning: Adapting the Model

- ▶ Once the foundational model is pre-trained, it is fine-tuned for specific tasks (e.g., sentiment analysis, question answering).
- ▶ **Intuition:** This is like taking a fluent English speaker and giving them a few examples to quickly learn how to classify movie reviews as positive or negative.
- ▶ This approach drastically reduces training time and data requirements compared to training a model from scratch.

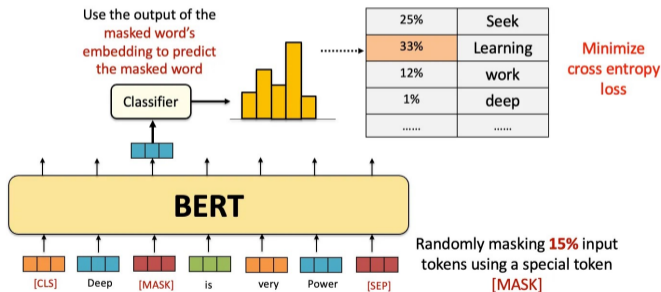

BERT Architecture

- ▶ BERT is built on the Transformer, leveraging **self-attention mechanisms** to generate contextualized word representations.
- ▶ This design enables BERT to learn context-dependent embeddings and capture relationships between sentences.
- ▶ Its training on the Transformer features **Masked Language Model (MLM)** and **Next Sentence Prediction (NSP)**.

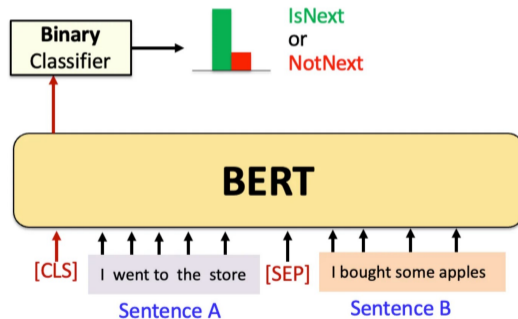

Pre-training: Masked Language Model (MLM)

- ▶ In MLM, BERT randomly masks 15% of the tokens in a sentence.
- ▶ **Example:** “Deep [MASK] is very powerful.”
BERT predicts the masked word as “Learning” or “Seek” based on context.

Pre-training: Next Sentence Prediction (NSP)

- ▶ **NSP** trains BERT to predict whether two sentences are consecutive.
- ▶ **Example:**
 - ▶ Sentence A: "I went to the store."
 - ▶ Sentence B: "I bought some apples."

This joint optimization of **MLM** and **NSP** enables BERT to learn both contextualized representations and inter-sentence relationships.

Input Representation: Embedding Components

- ▶ To support MLM and NSP, BERT's input representation handles not only words but also sentences, and not only single sentences but also sentence pairs.
- ▶ Each input token is represented as a combination of three embeddings:
 - ▶ **Token Embeddings:** Represent the actual word or subword units (e.g., "playing" → ["play", "ing"]).
 - ▶ **Segment Embeddings:** Differentiate between two sentences in a pair.
 - ▶ **Position Embeddings:** Encode the position of each token to preserve order.

Special Tokens & Downstream Performance

- ▶ Special tokens are added to the input sequence:
 - ▶ **[CLS]**: Placed at the beginning for classification tasks.
 - ▶ **[SEP]**: Used to separate sentences.

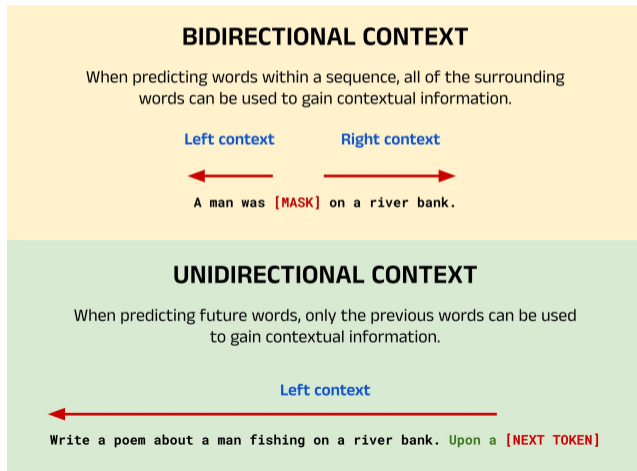

BERT's Bidirectional Context: Understanding from Both Sides

- ▶ BERT incorporates context from both the left and right of each word in an input sequence.
- ▶ **Intuition:** Imagine trying to guess a missing word with only one half of the sentence—it's much harder than using the full sentence to understand the meaning.
- ▶ In contrast, unidirectional models like GPT can only use preceding context, limiting their ability to fully understand word meaning in context.

BERT vs. GPT: A Visual Comparison

- ▶ **Key Difference:** BERT's bidirectionality allows it to capture more nuanced context, while GPT's unidirectional approach is tailored for text generation.

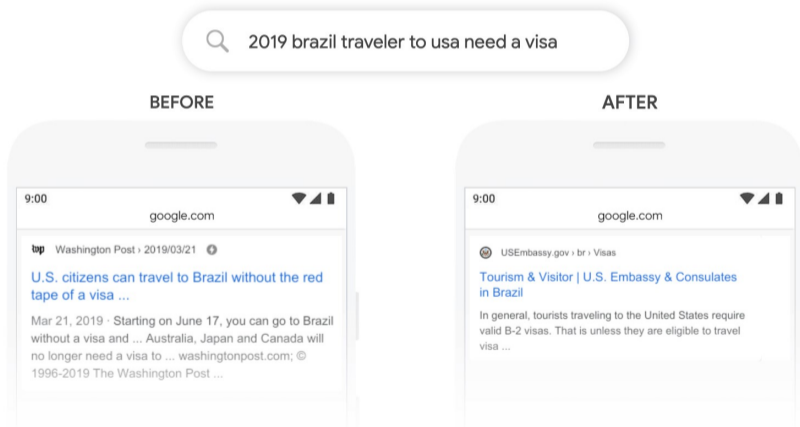

Popular BERT Applications: Overview

- ▶ **Google Search:** Enhances query understanding and relevance ranking.
- ▶ **Sentiment Analysis:** Captures nuanced sentiment by understanding context.
- ▶ **Question Answering:** Precisely extracts answers from large documents.
- ▶ **Named Entity Recognition:** Identifies and classifies entities with context.
- ▶ **Document Classification & Recommendation:** Improves categorization and matches user queries to relevant content.

BERT in Google Search

- ▶ **Enhanced Query Understanding:** BERT interprets the full context of search queries, even for ambiguous terms.
- ▶ **Improved Ranking:** By capturing subtle nuances, BERT helps rank results based on true user intent.

BERT for Sentiment Analysis

▶ Customer Feedback Analysis:

- ▶ Fine-tune BERT to classify customer reviews, tweets, and social media posts as positive, negative, or neutral.
- ▶ Companies use these insights to adjust marketing strategies and improve products.

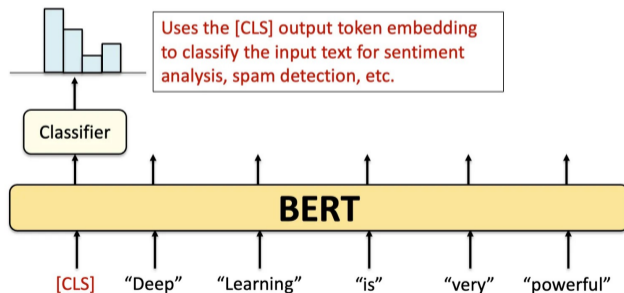

▶ Brand Monitoring:

- ▶ Real-time sentiment analysis of social media helps brands quickly detect and address potential PR issues.

BERT for Sentiment Analysis: the Role of Finetuning

- ▶ Leverage BERT's pre-trained contextual knowledge by adding a task-specific classification head (dense layer on [CLS]) for sentiment analysis.
- ▶ Fine-tune only the top layers on a small labeled dataset to efficiently capture domain-specific sentiment patterns.

BERT for Smart Recommendation

- ▶ **User Inputs and Movie Data:** Each user has a profile detailing preferred genres, and the system has a dataset of movies with descriptions.
- ▶ **Embedding Creation (BERT):** Both the user profile text and each movie's textual information are converted into numerical vectors via BERT, capturing semantic relationships in a shared embedding space.
- ▶ **Similarity Computation:** The model computes similarity (e.g., cosine similarity) between a user's embedding and each movie's embedding.
- ▶ **Recommendation Output:** Movies with the highest similarity scores to the user's embedding are presented as top recommendations.

Overview: Topic 9

- 1 BERT
- 2 GPT: Hallucination**
- 3 GPT: Introduction to RAG
- 4 Lab 7: Sentiment Analysis on Tweets

Hallucination in GPT: Understanding the Causes

- ▶ **Definition:** Hallucination occurs when GPT generates details or information that are not directly supported by the given input data or factual sources.
- ▶ **Common Causes:**
 - ▶ **Incomplete or Biased Training Data:**
 - ▶ GPT learns from a vast array of text, and if this data is missing essential context or reflects certain biases, the model might produce nonfactual outputs.
 - ▶ **Overgeneralization from Learned Patterns:**
 - ▶ The model may overgeneralize learned patterns, occasionally generating inaccurate or extraneous information.
 - ▶ **Lack of Explicit Factual Grounding:**
 - ▶ Lacking external fact-checking, GPT relies solely on its training data, sometimes generating creative yet unverified details.

Techniques to Reduce Hallucination

- ▶ **Mitigation Strategies:** Enhance data quality and preprocessing, refine model architecture and parameters, and employ reinforcement learning from human feedback to minimize hallucinations and improve factual accuracy.
- ▶ **External Knowledge Integration:** Retrieval-augmented generation to verify and supplement responses with up-to-date facts.
- ▶ **Improved Context Understanding & Chain-of-Thought:** Better long-context tracking and step-by-step reasoning to avoid unsupported details.
- ▶ **User Prompts & Instructions:** Clear guidelines for the model to express uncertainty rather than fabricating information.
- ▶ **Post-Generation Fact-Checking:** Validate outputs using independent tools or human review.

One-Shot Prompting

- ▶ **Concept:** Provide a single example along with the task instructions.
- ▶ **Usage:** Ideal when one clear example suffices to define the task.

Task: Convert temperatures from Fahrenheit to Celsius

Example:

Input: Convert 68°F to Celsius.

Output: 20°C.

Few-Shot Prompting

- ▶ **Concept:** Provide multiple examples along with the task instruction.
- ▶ **Usage:** Effective when the task requires a pattern or specific format that benefits from multiple illustrations.

Task: Extract keywords from a text

Example 1:

Text: "Stripe offers payment APIs for web developers."

Keywords: Stripe, payment, APIs, web developers

Example 2:

Text: "OpenAI develops cutting-edge language models for diverse applications."

Keywords: OpenAI, language models, applications

Now:

Text: {Your Text Here}

Keywords:

Chain-of-Thought Prompting

- ▶ **Purpose:** Prompt the model to detail its reasoning process step-by-step before giving the final answer.
- ▶ **Usage:** Particularly useful in scenarios requiring logical reasoning or multiple steps to arrive at the correct answer.

Task: Solve a Math Problem

Prompt:

"Question: If you have 25 apples and you give away 7, then buy 10 more, what is your total number of apples?"

Let's think step-by-step:

1. Start with 25 apples.
2. After giving away 7, you have $25 - 7 = 18$ apples.
3. Then you buy 10 more apples, making it $18 + 10$.

Final Answer: "

Prompt Engineering Examples

Zero-Shot

Prompt:

Q: The cafeteria had 23 apples. If they used 20 to make lunch and bought 6 more, how many apples do they have?

Response:

A: 27 

Few-Shot

Prompt:

Q: Roger has 5 tennis balls. He buys 2 more cans of tennis balls. Each can has 3 tennis balls. How many tennis balls does he have now?

A: The answer is 11.

Q: The cafeteria had 23 apples. If they used 20 to make lunch and bought 6 more, how many apples do they have?

Response:

A: The answer is 27 

Few-Shot-CoT

Prompt:

Q: Roger has 5 tennis balls. He buys 2 more cans of tennis balls. Each can has 3 tennis balls. How many tennis balls does he have now?

A: Roger started with 5 balls. 2 cans of 3 tennis balls each is 6 tennis balls. $5+6=11$. The answer is 11.

Q: The cafeteria had 23 apples. If they used 20 to make lunch and bought 6 more, how many apples do they have?

Response:

A: The cafeteria had 23 apples originally. They used 20 to make lunch. So they had $23-20=3$. They bought 6 more apples, so they have $3+6=9$. The answer is 9. 

Zero-Shot-CoT

Prompt:

Q: The cafeteria had 23 apples. If they used 20 to make lunch and bought 6 more, how many apples do they have?

A: Let's think step by step.

Response:

A: The cafeteria had 23 apples originally. They used 20 to make lunch. So they had $23-20=3$. They bought 6 more apples, so they have $3+6=9$. The answer is 9. 

Meta-Prompting

- ▶ **What it is:** a prompt that creates or improves another prompt.
- ▶ **Why it is powerful:** it turns vague requests into structured, reusable instructions.
- ▶ **What it adds:** role, process, inputs, output format, constraints, and checks.

Key Idea

Instead of asking the model to *do the task immediately*, you first ask it to *design the best prompt for the task*.

A Very Simple Example

Meta-Prompt Example

Meta-Prompt:

“Turn my goal into a clear, ready-to-use prompt. Include role, tone, output format, and constraints.”

User Goal:

“I need a polite email asking a professor for a meeting.”

Generated Prompt:

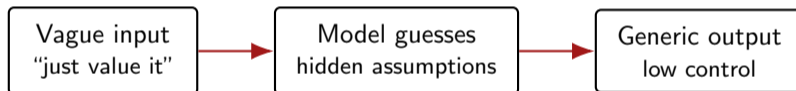

“You are a professional email assistant. Draft a short, polite email to a professor asking for a 20-minute meeting next week. Tone: respectful. Length: under 120 words.”

- ▶ The meta-prompt does not write the email.
- ▶ It writes a better prompt for writing the email.

The Paradox: Saving Effort Can Worsen Results

What goes wrong

If you outsource thinking to the LLM, it must **guess more** → outputs become more **generic** and more **“AI-flavored.”**

Takeaway

The goal is not “let AI think for you” — it is to let AI **execute your thinking process**, then reuse it.

Overview: Topic 9

- 1 BERT
- 2 GPT: Hallucination
- 3 GPT: Introduction to RAG**
- 4 Lab 7: Sentiment Analysis on Tweets

LLM Limitations in Business Applications

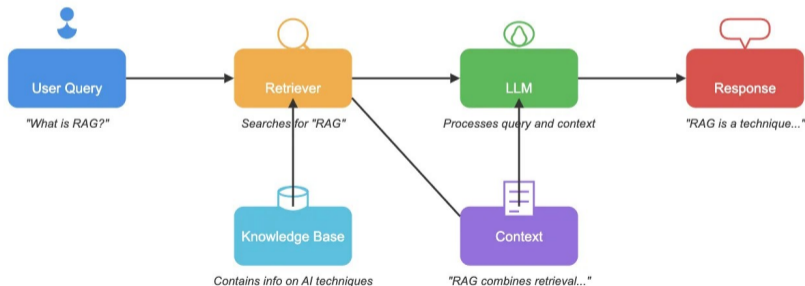

- ▶ Large Language Models (LLMs) like GPT-5, Gemini, Claude, Deepseek enable powerful NLP capabilities.
- ▶ Hallucination: LLMs may generate plausible-sounding but incorrect or fabricated information
- ▶ Static knowledge (training cutoff): limits currency (e.g., ChatGPT-4o unaware of 2025 events).
- ▶ Two methods to augment and specialize LLMs:
 - ▶ **Retrieval-Augmented Generation (RAG)** – improves inputs at inference.
 - ▶ **Fine-Tuning** – updates model parameters at training.

What is Retrieval-Augmented Generation (RAG)?

- ▶ Introduced by Meta (2020), RAG connects an LLM with an external, dynamic knowledge base.

Retrieval-Augmented Generation (RAG) Process

Example: Answering "What is RAG?"

RAG in Corporate Valuation

- ▶ Example Knowledge Base for Corporate Valuation:
 - ▶ Public companies' financial filings (10-K, 10-Q)
 - ▶ Conference call transcripts
 - ▶ Real time price and trading data
- ▶ Process:
 1. Query triggers retrieval from external database.
 2. Retrieved context combined with original query.
 3. LLM generates response using combined information.

RAG in Corporate Valuation

Example: Real-Time Valuation AI agent

A valuation chatbot queries "What is Company X's latest ROIC guidance?":

- ▶ Retriever fetches MD&A (Item 7) from most recent 10-K and Q4 call transcript.
- ▶ LLM synthesizes retrieved guidance and model knowledge to deliver precise ROIC estimate.
- ▶ No retraining needed when new filings released.
- ▶ Advantage 1: keeps LLM up-to-date (e.g., real-time valuation adjustments from latest earnings calls).
- ▶ Advantage 2: Substantially limits hallucination

Overview: Topic 9

- 1 BERT
- 2 GPT: Hallucination
- 3 GPT: Introduction to RAG
- 4 Lab 7: Sentiment Analysis on Tweets**

Lab 7: Sentiment Analysis on Tweets

Motivation for Sentiment Analysis on Tweets

- ▶ **Why Sentiment Analysis?**
 - ▶ Helps understand public opinion and customer sentiment.
 - ▶ Critical for businesses and investors to gauge market trends.
- ▶ **Why Tweets?**
 - ▶ Tweets are short, timely, and widely available.
 - ▶ They capture real-time reactions and public mood.
- ▶ **Application Example:**
 - ▶ Analyzing Tesla's tweets to correlate sentiment with stock price movements.

BoW-Based Sentiment Analysis: Overview

▶ **Concept:**

- ▶ Represent each tweet as a vector of word counts.
- ▶ Use a sentiment dictionary to assign sentiment scores.

▶ **Steps:**

- ▶ Preprocess tweets (cleaning, tokenization).
- ▶ Build a Bag-of-Words model (create a vocabulary, count word occurrences).
- ▶ Apply a sentiment dictionary (e.g., VADER) to score each tweet.

▶ **Intuition:**

- ▶ This method is simple and interpretable, though it ignores word order and context.
- ▶ Aggregate scores for the tweet.

Fine-Tuning BERT: Preprocessing and Setup

▶ **Data Preparation:**

- ▶ Use your preprocessed tweet dataset.
- ▶ Tokenize the tweets with BERT's tokenizer to convert text into token IDs.

▶ **Fine-Tuning:**

- ▶ Use a small, labeled sentiment dataset to fine-tune BERT.
- ▶ Modify the output layer (classification head) according to your task (e.g., binary sentiment: positive/negative).

▶ **Intuition:**

- ▶ Fine-tuning adapts the pre-trained language model to capture task-specific sentiment signals.

Fine-Tuning BERT: Training and Evaluation

- ▶ **Training Process:**
 - ▶ Initialize with pre-trained BERT weights.
 - ▶ Train the model on the labeled sentiment data.
- ▶ **Evaluation:**
 - ▶ Assess performance using metrics like accuracy, precision, recall, and F1-score.
 - ▶ Compare against the dictionary-based BoW approach to highlight improvements.
- ▶ **Intuition:**
 - ▶ BERT's context-aware embeddings allow it to better understand sentiment even in complex, nuanced tweets.
